Gravity Survey along the Lines of Precise Levels throughout Japan by Means of a WORDEN Gravimeter.

Part IX. Kyûshû District.

By Chuji TSUBOI, Akira JITSUKAWA and Hirokazu TAJIMA,

Earthquake Research Institute.

CONTENTS

1. Introduction

Since the spring of 1951, the writers have been engaged in an extensive gravimeter survey along the entire length of the lines of precise levels throughout Japan by means of a Worden gravimeter. The network of the lines of precise levels belonging to the Geographical Survey Institute covers the whole country densely as was shown in Fig. 1 of Part I, and it reaches approximately 20,000 km. in total length. The bench marks are laid at an average distance of 2 km. measured along these level lines. In the present survey, the gravity values have been determined at every other one of these bench marks, that is at intervals of 4 km. The results of the gravimeter measurements that were obtained in the Shikoku, Chûgoku, Kinki, Chûbu, Tôhoku and Kantô Districts have already been published as Parts I, II, III, V, VI, VII and VIII of these serial reports (Tsuboi et al.: 1953, 1954, 1955, 1956). The present report is the ninth in the series and is particularly concerned with the results obtained in the Kyûshû District (Tsuboi et al: 1954).

2. Lines of Precise Levels in the Kyûshû District

The Kyûshû District is essentially Kyûshû Island, situated in the south-western part of the Japanese islands as shown in Fig. 1.
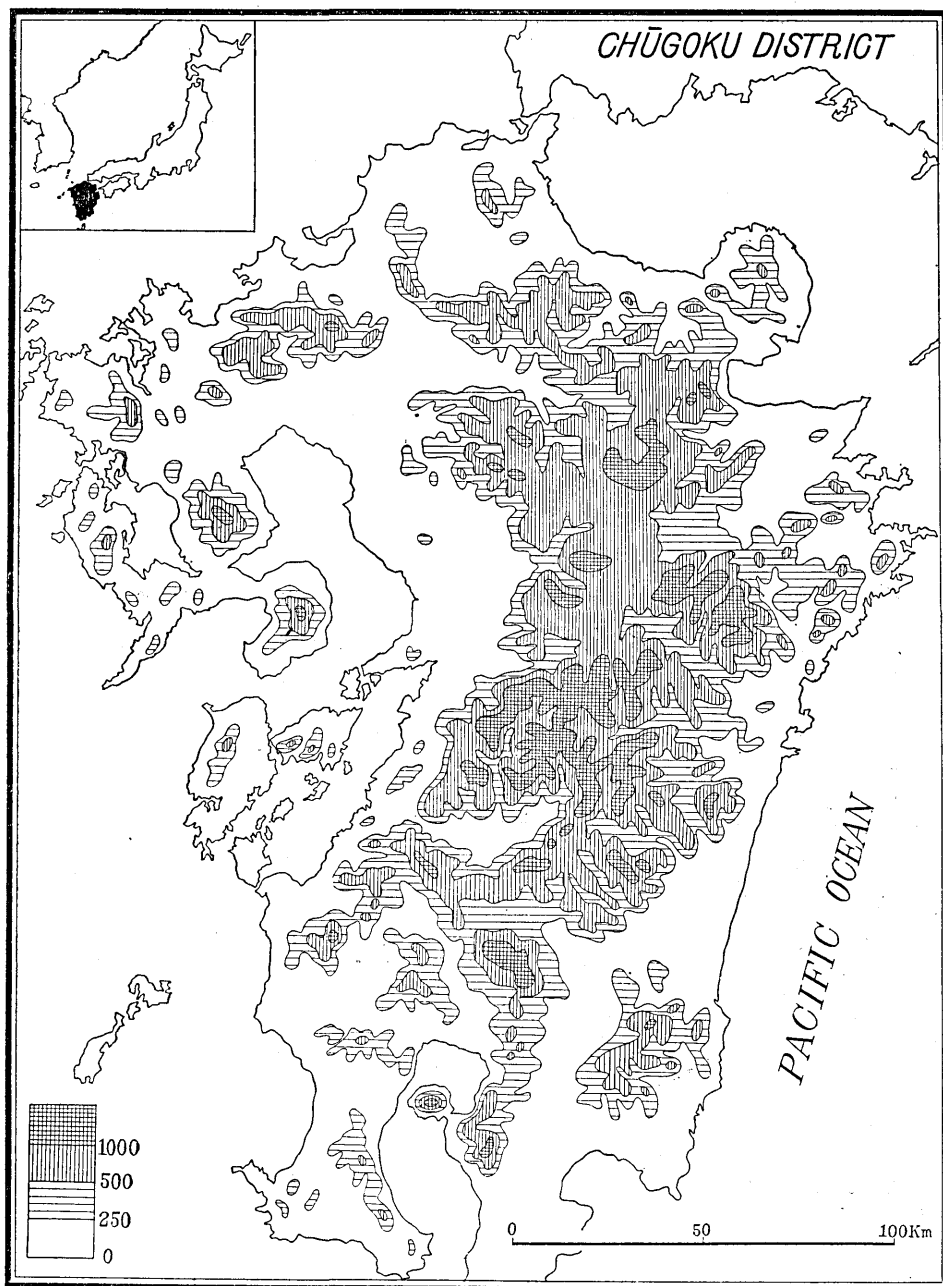

Fig. 1. Topographical Map of the Kyûshû District.

The District is roughly a pentagon in shape, more or less elongated in the NS direction. It is approximately 44,500 km² in area. Fig. 1 shows the topography of the District roughly.

The Kyûshû District comprises seven administrative prefectures, viz., (39) Fukuoka, (40) Saga, (41) Nagasaki, (42) Kumamoto, (43) Ôita, (44) Miyazaki and (45) Kagoshima. The network of the lines of precise levels in this District, along which the gravity survey was made, is shown in Fig. 2, together with the prefecture boundaries. The level lines are altogether about 2,200 km. in length and the gravity values were determined at 538 points along them. In this number are also included several identifiable points such as local weather stations, of which the heights are known with sufficiently high accuracy for the purpose of our gravity reductions. The number of points at which the gravity values were determined in each of the prefectures is given in Table I.

Table I.
Number of Gravimeter Stations.

Prefecture	Number
(39) Fukuoka	67
(40) Saga	34
(41) Nagasaki	65
(42) Kumamoto	103
(43) Ôita	72
(44) Miyazaki	92
(45) Kagoshima	105
Total	538

The gravimeter survey in this District was made in various periods, namely, in May, 1953, and in Feb. and May, 1954.

3. Methods of Measurements and Reductions

Since the methods of measurements and reductions are the same as those already stated in the previous reports, no repeated description will be necessary, nor further comments need be added. The one important ·thing which must be mentioned is that no attempt has been made here, as in the previous reports, to adjust the measured gravity values by simultaneous net calculations. The whole length of the lines of measurements is actually a connected chain of many small gravimetric loops, for each of which the drift rate of the gravimeter spring was determined severally. These small loops are numbered as illustrated in Fig. 2. After the relative gravity values at the sites of bench marks situated along each of the loops were determined separately, the results were merely connected in succession. This procedure is admittedly not a kind from which very accurate results can be expected, but unavoidable circumstances regarding transportation facilities on the one hand and the rather hasty demand for getting a picture of the distribution

of the gravity anomalies on the other, caused the adoption of this procedure as the second best. Although we do not claim that the results given in this report are of the highest attainable accuracy, it is not likely that any difference in the procedure of reduction will alter the final results sensibly.

The Kyûshû District is essentially an island separated from Honshû, the main island, by a strait less than 1 km in width which is famous for its swift tidal currents. Beneath this strait, a highway goes through a tunnel and connects Honshû and Kyûshû. It is by comparing the gravity values at the two bench marks on the opposite sides of the tunnel that Honshû and Kyûshû were connected gravimetrically. The result of these connection measurements is summarised in Table II.

Table II. Gravimetric Connection of the Kyûshû and Chûgoku Districts.

B.M.	Date	Time		SD	$\dfrac{SD \times}{0.9150}$	E.T.	h		Drift		δg	979.
		h m	h m									
1779 (Kyûshû)	V 13, 1953	9 25	0 00	1136	1039	5	31	1075	0	1075	—	67488
1772 (Honshû)	″	11 24	1 59	2224	2035	17	−8	2044	19	2025	+950	68438 (given)
1779 (Kyûshû)	″	12 47	3 22	1155	1057	18	33	1108	33	1075	—	67488

It is already known that the value of g at B.M. 1772 (Honshû) is 979.68438, and by means of this tie between Kyûshû and Honshû, g at B.M. 1779 (Kyûshû) has been determined to be 979.67488. The gravity values at all other stations in Kyûshû are referred to the value at this point.

Our Worden gravimeter has been working with an admirable perfection, only the rate of drift of the gravimeter spring differed notably from one loop to others. It will be interesting to compare the rates for various loops given in Table III.

4. Results

The gravity values at all the stations in this District are given in Table IV–VIII for each of the loops separately. In Table IX–XV, the materials are arranged synoptically according to the seven prefectures of the District individually. The explanations of the tables precede them. The lines of equal Bouguer anomalies based on the International Gravity Formula are shown in Fig. 3 with 2 mgal. intervals. The figure is in the pocket attached to the back cover of the present report. The locations of the contour lines are accurate where they meet the lines

of precise levels, but obviously no great accuracy can be claimed for those in the intervenient parts. Fig. 4 is a simplified map showing the same distribution with 5 mgal. intervals.

Reserving the detailed and quantitative geophysical interpretations of the distribution of BOUGUER anomalies for future studies, we will briefly enumerate the especially notable facts to be observed in Figs. 3 and 4.

Table III. Apparent Rate of Drift of the Gravimeter Spring for Various Loops.

1) As a whole, the BOUGUER anomaly increases systematically toward the western and northern coasts of the island. The +30 mgal. line, for instance, runs approximately along the coast line and beyond that line, the anomaly increases seaward. Gravity pendulum data obtained by N. KUMAGAI (1942) at a few points on the Gotô Islands also indicate this increase. The sea to the west of the island is a marginal part of the Yellow Sea. Since the Sea is only a few hundred meters in depth, it has been believed to be " continental " rather than " oceanic " in character. But the fact that the BOUGUER anomaly does
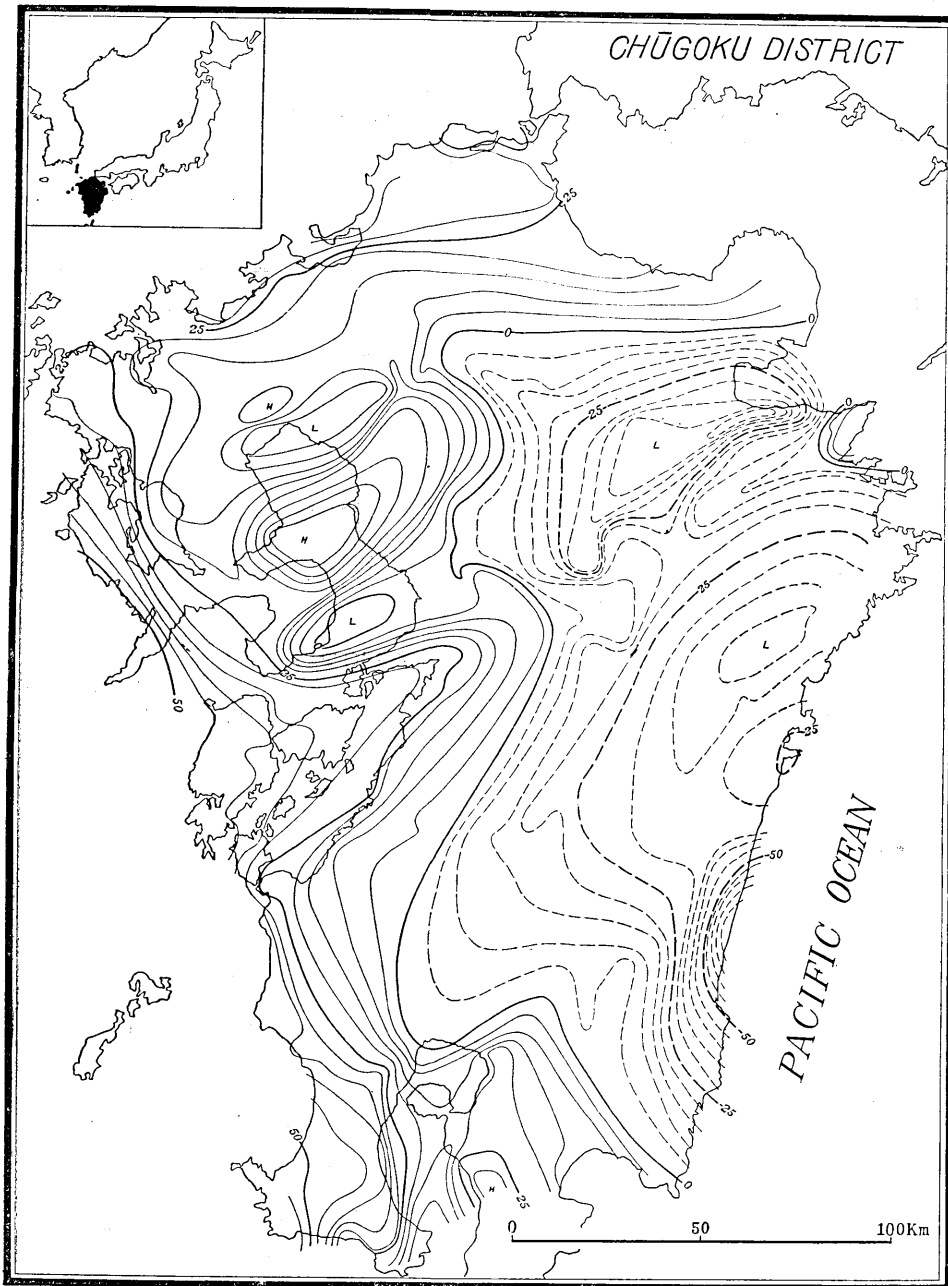

Fig. 4. Simplified Map Showing the Bouguer Anomaly Distribution in the
    Kyûshû District (5 mgal. interval. Full line: positive anomaly, Broken
    line: negative anomaly.)

increase notably seaward here might suggest that this is perhaps not the case.

According to the gravity measurements in China by P. R. LEJAY (1936), the BOUGUER anomaly increases toward the Yellow Sea also. The increase of the anomaly toward the Yellow Sea on both sides appears to mean that the denser subcrustal material lies closer to the earth's surface under the Yellow Sea than it does in the normally "continental" area, or in other simple words that the Sea is "oceanic". But why its shallowness?

That the Sea here is shallow is likely to mean that a very thick layer of deposit or sediments of loose material covers the bottom of the Sea, which would otherwise be deep as shown in Fig. 5. A large river, the Yang-tze-kiang, flows into the Yellow Sea, transporting a tremendous amount of sand, mud, clay, etc. S. HAYAMI, estimates the annual mass transported by the river is well over 3×10^8 tons/year. If this enormous quantity of deposits is evenly spread over an area of 5×10^5 km² to form a layer having the density 2.0 on the sea bottom, the rate of growth of this sedimentary layer will be about 3×10^{-4} m/year. So in the course of 10^7 years, it will easily grow up to attain a thickness of 3×10^3 m and it is not difficult to make this part appear as if it were a part of a continent. The writers do not believe this is an absurd estimation.
Fig. 5. Profile Showing the Supposed Underground Structure of the Yellow Sea.

2) The approximate parallelism of the isoanomaly line and the western coast line of the island fails at about the middle of the island where the gravity high is seen to protrude from west to east into the backbone area of the island. This ridge of gravity high can be traced still further eastward, although the gravity high itself gradually decreases in amount, even becoming negative. A little to the east of the central axis of the island, there are two areas of negative gravity anomaly on the northern and southern sides of this ridge of gravity high. At this place, the gravity high takes a minimum value so that the distribution of anomaly here represents a saddle form. After this saddle point is passed, the gravity high begins to increase again in amount eastward. Thus, this ridge of gravity high is very clearly seen to run

across the island of Kyûshû in the E-W direction. Along the northern side of this ridge, the anomaly decreases steeply northward. It is about along this zone that the Median Tectonic Line has been supposed to run, although its exact location has not been possible geologically, owing to thick volcanic ejecta which cover the area widely. Our gravity survey has established the existence of this line beyond doubt, although nothing definite can yet be said as to the geophysical structure that will cause the observed gravity anomalies. It is interesting to note that small earthquakes occur frequently throughout this zone.

3) Along the northern coast of Kyûshû, the isoanomaly lines are approximately parallel to the coast line as was stated before. The area lying between this belt of parallelism and the ridge of gravity high mentioned in the last section is triangular in form and the isoanomaly lines are rather irregularly shaped within it. From this point of view, the whole area of Kyûshû may be divided into three parts, A, B and C, as shown in Fig. 6. In area A, the isoanomaly lines are approximately parallel to the northern coast line of the island; in area B, the lines are irregularly shaped; in area C, the trends of the isoanomaly lines are more or less systematic. It is noteworthy that the isoanomaly lines which run in the E-W direction in area A and which are parallel to the northern coast line of the island turn sharply northward near the eastern end of the area and are connected in a natural way with the isoanomaly lines in the Chûgoku District. It is also noteworthy that there is no gravimetric indication that the ridge of gravity high bounding the areas B and C continues to run further westward into the Yellow Sea.

Fig. 6. A, B and C Areas in the Kyûshû District.

4) In area C, the gravity anomaly decreases more or less systematically eastward and at a certain point on the east coast, an anomaly of −72 mgals. is found. The isoanomaly lines are approximately elliptic around this minimum and suggest a conspicuous depression of the earth's crust at this place. It is here that many good sized earthquakes occur frequently.

ウォルドン重力計による日本全国の重力測定
第九報 （九州地方）

坪井忠二・実川　顕・田島広一

これは，九州地方538点における重力測定結果をまとめたものである．測定と計算との方法は，第1報に述べてあるのとほとんど同じであるから，ここにはくりかえさない．結果は第 IV 表～第 VIII 表（ルート別），第 IX 表～第 XV 表（県別）に示してある．ブーゲー異常の分布は，第3図にくわしく示してある．第4図はその略図である．

これらの図からわかる主なことがらは，次のとおりである．

1) ブーゲー異常は，大きくみて，西方と北方とへ向かつて大きくなつている．例えば +30 ミリガルの線は，西と北との海岸線にほぼ平行に走り，それよりも外側，すなわち海側では，異常は大きくなる．五島列島の数点における熊谷教授の測定結果も，このことを示している．黄海の深さはせいぜい数100ｍであつて，ここは“海”であるよりは“陸”であると考えられていた．しかし，ブーゲー異常が黄海海岸に向かつて増していることからみると，この考えは正しくないのかも知れない．

中国大陸における R. P. LEJAY の測定結果も，ブーゲー異常がやはり黄海々岸に向かつて増していることを示している．

以上の事実を綜合して考えると，黄海は実は“海”であるのかも知れない．そしてそれが浅いのは，楊子江が運び込む土砂が海底に厚く堆積しているからであるかも知れない．(第5図)．楊子江が運び込む土砂の量は，速水教授によれば 3×10^8 トン/年 である．この土砂が $5 \times 10^5 \mathrm{km}^2$ の面積にわたつて散布されて，密度 2.0 の堆積層をつくるとすれば，その層の生長は $3 \times 10^{-4} \mathrm{m}$/年 であつて，$10^7$ 年の間には $3 \times 10^3 \mathrm{m}$ になり得る．

2) 等異常線と九州西海岸線とはほぼ平行であるが，八代海でその平行性は破れ，高重力のリッジが西から東へ入り込んで，九州中軸に達している．この高重力のリッジは更に東に追跡することができるが，高重力そのものは減り，マイナスにさえなる．九州の中軸を過ぎると，このリッジの北側と南側とに，ブーゲー異常マイナスの地域がみられる．ここからリッジに沿つて東へ向かうと，ブーゲー異常はまた増す．このように，このリッジは九州を東西の方向に横切つている．ブーゲー異常はこのリッジから北方へ向かつて急に減る．中央構造線が走つているであろうと考えられていたのはこの地帯である．この地域は，火山噴出物によつて厚くおおわれているので，この構造線は地質学的には見にくいとのことであるが，重力測定の結果は明らかになにらかの構造線が存在していることを暗示している．小区域地震がこの地帯に多いことは注目に値する．

3) 九州北岸では，等重力線と海岸線とにはほぼ平行である．この平行地帯と，前節の高重力リッジとの間は，ほぼ三角形であつて，その三角形の内においては，等重力線分布はだいぶ乱れている．この見方からすると，九州は第6図のように A, B, C の 3 つにわけられる．A では等重力線が北海岸線とほぼ平行，B では不規則，C では規則的にほぼ南北に走る．

北海岸線にほぼ平行な等重力線は，東の端でむきを急に北に変えて，中国地方の等重力線に自然に連なる．また B と C とを境する高重力リッジが，更に西へ黄海へまでのびている形跡はない．

4) C の内では，ブーゲー異常は東へ向かつて減つている．宮崎県の東海岸宮崎市の近くには，−72 ミリガルという点がある．そして等異常線はここを中心とした楕円形をなしており，地殻のいちじるしい陥没を示している．顕著地震・稍顕著地震が，この近くに頻発することは注目に値する．
