Gravity Survey along the Lines of Precise Levels throughout Japan by Means of a WORDEN Gravimeter.

Part VIII. Kantô District.

By Chuji TSUBOI, Akira JITSUKAWA and Hirokazu TAJIMA,
Earthquake Research Institute.

(Read May 19, 1953.—Received Feb. 20, 1956.)

CONTENTS

1. Introduction

Since the spring of 1951, the writers have been engaged in an extensive gravimeter survey along the entire length of the lines of precise levels throughout Japan by means of a WORDEN gravimeter. The net work of the lines of precise levels belonging to the Geographical Survey Institute covers the whole country densely as was shown in Fig. 1 of Part I, and it reaches approximately 20,000 km. in total length. The bench marks are laid at an average interval of 2 km. measured along these level lines. In the present survey, the gravity values have been determined at every other one of these bench marks, that is at intervals of 4 km. The results of the gravimeter measurements that were obtained in the Shikoku, Chûgoku, Kinki, Chûbu and Tôhoku Districts were already published as Parts, I, II, III, V, VI, and VII of these serial reports (TSUBOI et al.: 1953, 1954, 1955, 1956). The present report is the eighth in the series and is particularly concerned with the results obtained in the Kantô District (TSUBOI et al.: 1954).

2. Lines of Precise Levels in the Kantô District

The Kantô District occupies the southeastern part of Honshû, the main island of Japan as shown in Fig. 1. The District is roughly a square in shape with its sides 150 km. in length. It is approximately 32,200 km^2. in area. Fig. 1 also shows the topography of the District.

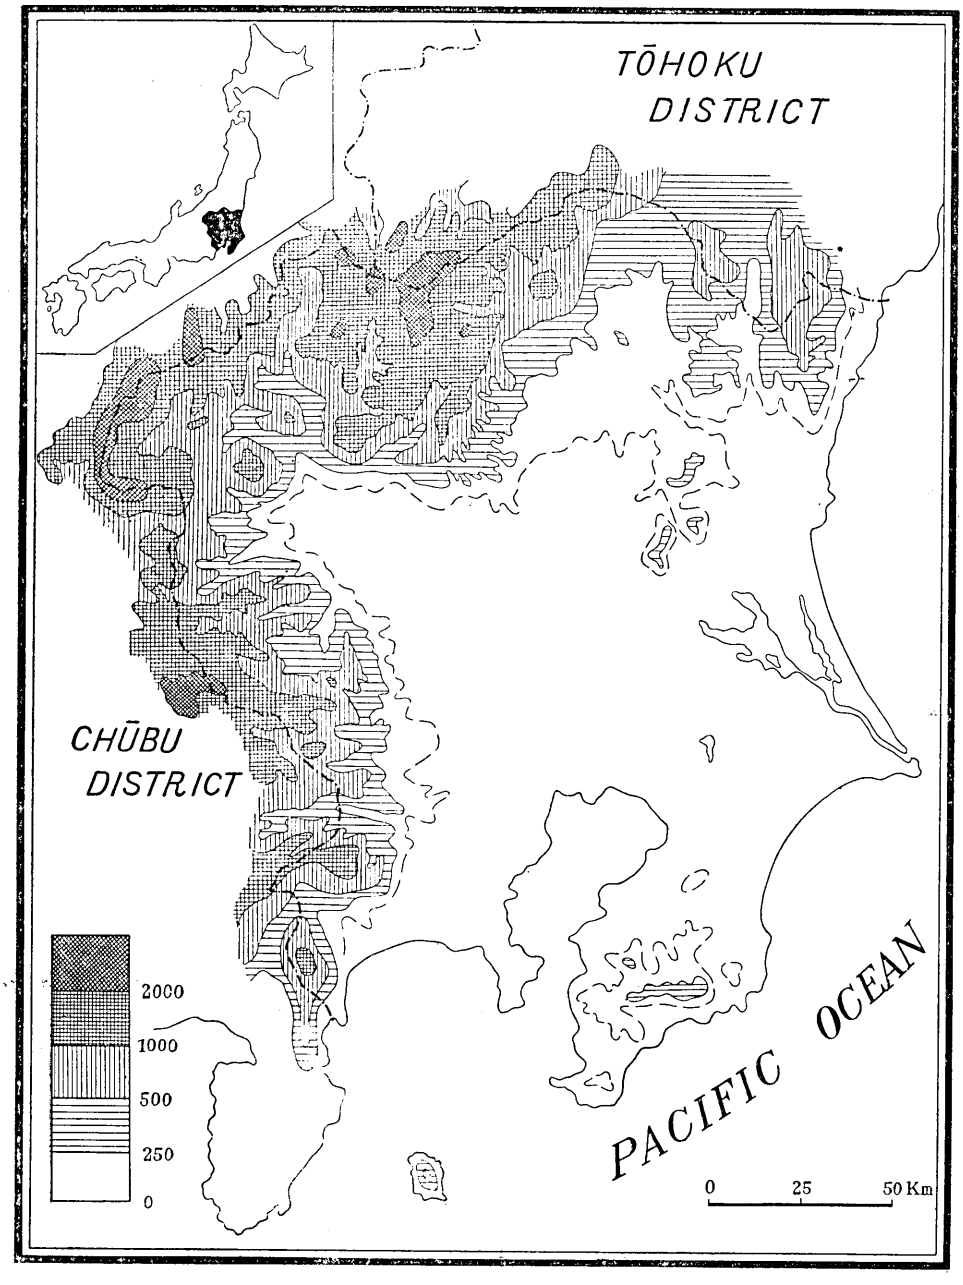

Fig. 1. Topographical Map of the Kantô District. (Height in m.)

Topographically, the District may be regarded as a large basin surrounded by mountains on all its sides except towards the east as can be seen from the map in Fig. 1. The low land which occupies the central part of the District is covered by Pleistocene and Recent geological formations and is the largest plain in the country.

The Kantô District comprises seven administrative prefectures, viz., (7) Ibaraki, (8) Tochigi, (9) Gumma, (10) Saitama, (11) Chiba, (12) Tôkyo and (13) Kanagawa. The net works of the lines of precise levels in this District, along which the gravity values were measured, are shown in Fig. 2 together with the prefecture boundaries. The lines are altogether about 1,500 km. in length, and at 366 points along them, the gravity values were determined. In this number are also included several identifiable points, such as local weather stations, of which the heights are known with sufficiently high accuracy for the purpose of our gravity reductions. The number of points at which the gravity values were determined in each of the seven prefectures is given in Table I.

Table I.
Number of Gravimeter Stations

Prefecture	Number
(7) Ibaraki	52
(8) Tochigi	60
(9) Gumma	41
(10) Saitama	40
(11) Chiba	112
(12) Tokyo	17
(13) Kanagawa	44
Total	366

The gravimeter survey in this District was made in various periods, namely, in January, February, March and July, 1952, and in February, March, April, July and October, 1953.

3. Methods of Measurements and Reductions

Since the methods of measurements and reductions are the same as those already stated in previous reports, no repeated description will be necessary, nor further comments need be added. The one important thing which must be mentioned is that no attempt has been made here, as in the previous reports, to adjust the measured gravity values by simultaneous net calculations. Actually, the whole length of the lines of measurements is a connected chain consisting of a number of small gravimetric loops, for each of which the drift rate of the gravimeter spring was determined severally. These small loops are numbered as illustrated in Fig. 2. After the relative gravity values at the sites of bench marks situated along each one of the loops were determined separately, the results were merely connected in succession. This procedure is admittedly

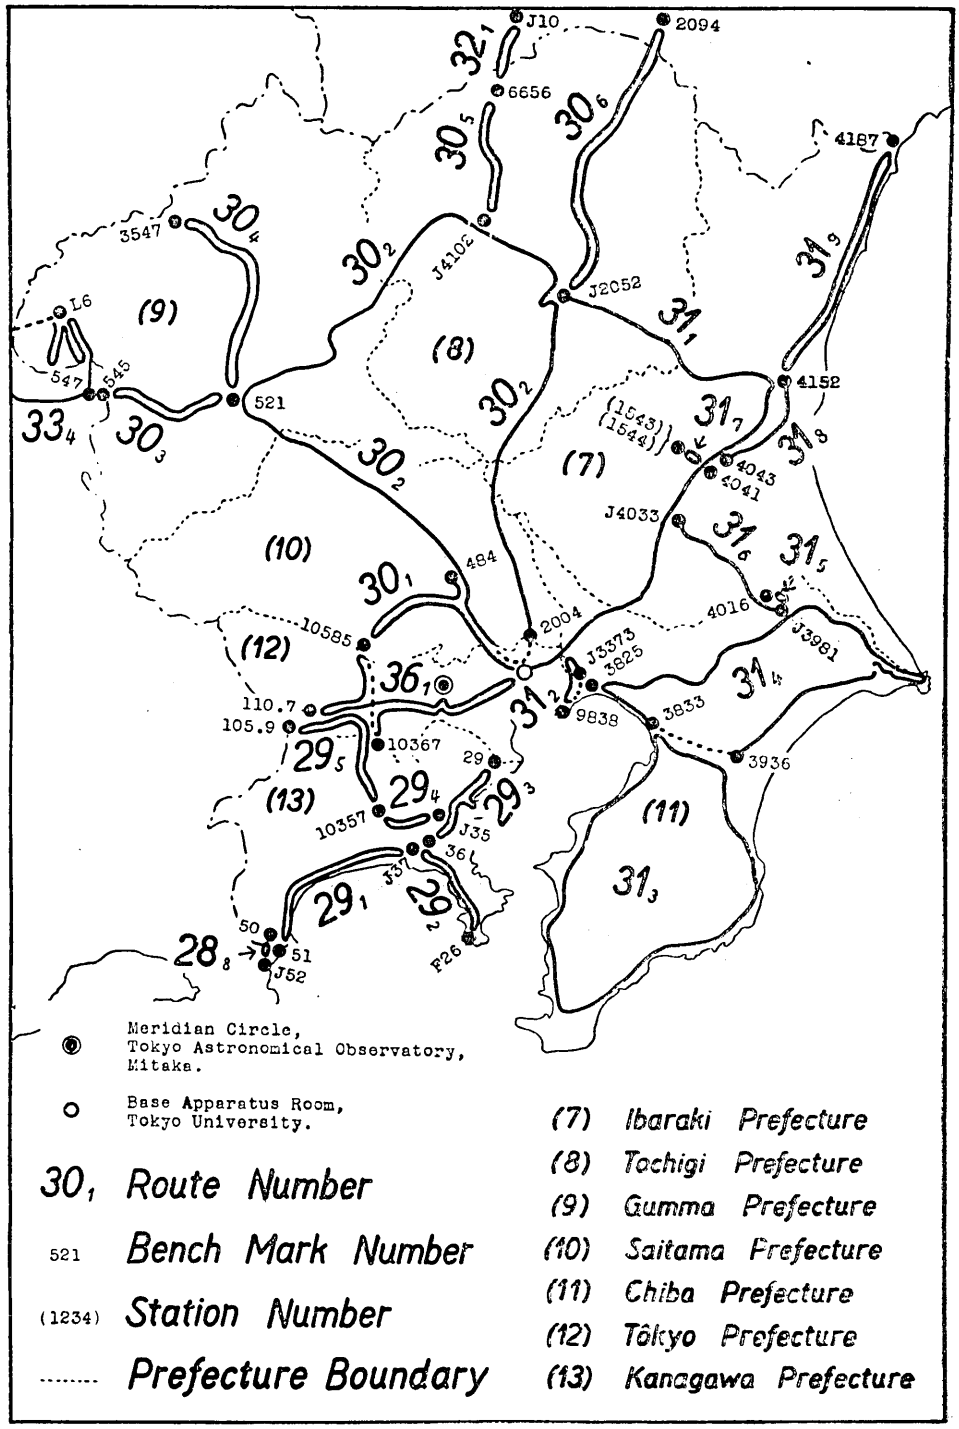

Fig. 2. Lines of Precise Levels in the Kantô District with the Prefecture Boundaries.

not a kind from which very accurate results can be expected, but unavoidable circumstances regarding transportation facilities on the one hand and the rather hasty demand for getting a picture of the distribution of the gravity anomalies on the other, have made us adopt this procedure as the second best. Although we do not claim that the results given in this report are of the highest attainable accuracy, it is not likely that any difference in the procedure of reduction will alter sensibly the final results. It is of course our wish to make a simultaneous net adjustment when the survey over the whole country is completely finished.

Our WORDEN gravimeter has been working with admirable perfection only the rate of drift of the gravimeter spring differed notably from one loop to another. It will be interesting to compare the rate for each of the loops given in Table II.

Table II. Apparent Rate of Drift of the Gravimeter Spring for Various Loops.

4. Results

The gravity values at all the stations in this District are given in Tables III∼IX for each of the loops separately. In Tables X∼XVI, the materials are arranged synoptically according to the seven prefectures of the District separately. The explanations of the tables precede

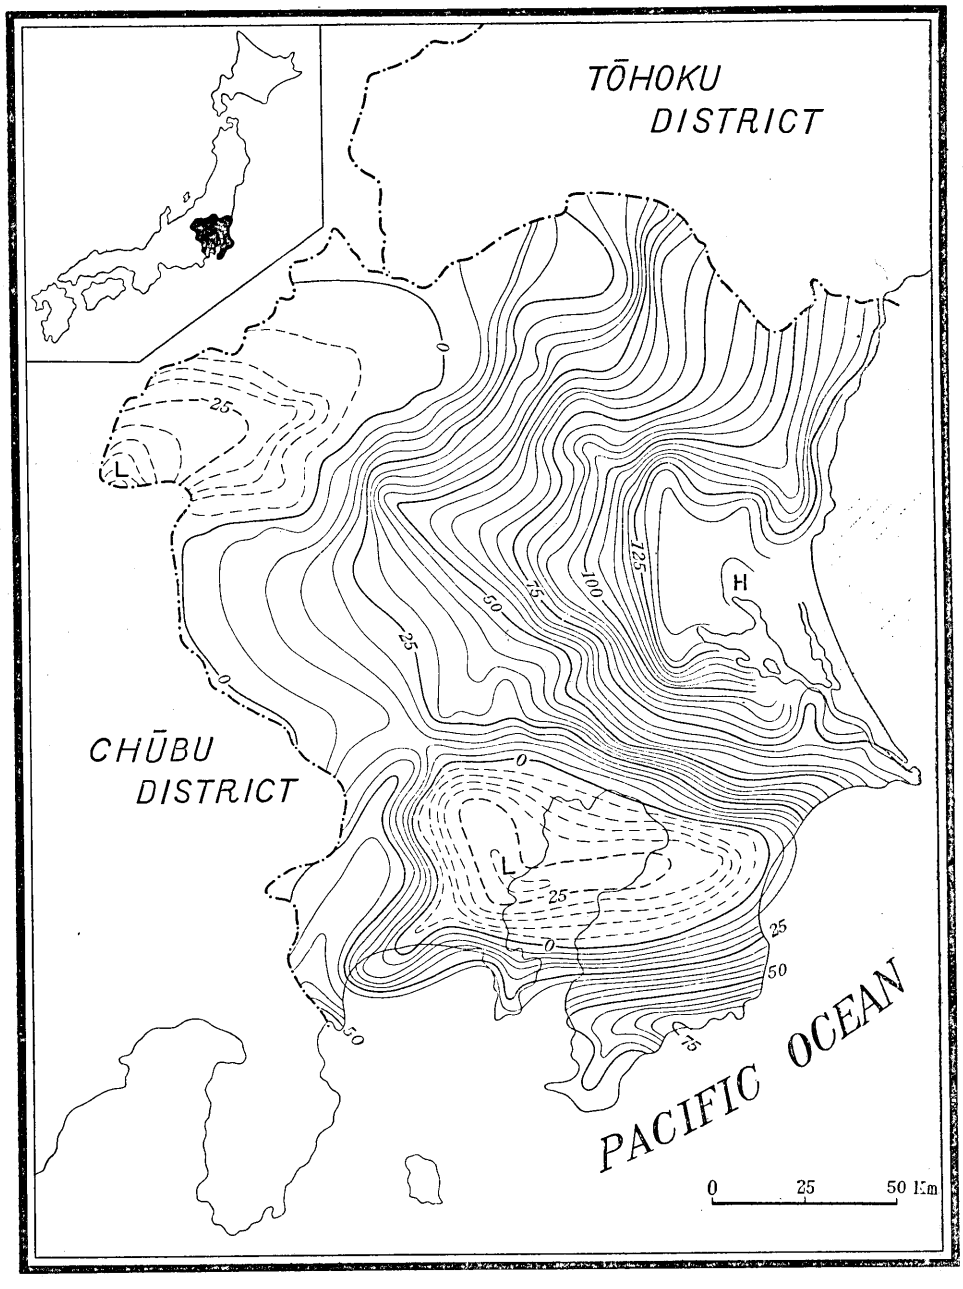

Fig. 4 Simplified Map Showing the BOUGUER Anomaly Distribution in the Kantô District. (mgal.)

them. The lines of equal BOUGUER anomalies based on the International Gravity Formula are shown in Fig. 3 with 2 mgal. intervals. The figure is in the pocket attached to the back cover of the present report. The locations of the contour lines are accurate where they meet the lines of precise levels, but obviously no great accuracy can be claimed for those in the intervenient parts. Fig. 4 is a simplified map showing the same distribution with 5 mgal. intervals.

Reserving the detailed and quantitative geophysical interpretations of the distribution of the BOUGUER anomalies for future studies, we will briefly enumerate the especially notable facts to be observed in Figs. 3 and 4.

1) Although the Kantô District is mostly a flat plain topographically, as was stated before, it is never flat from the gravimetric point of view and the distribution of the gravity anomalies in it is very much complicated. The highest anomaly is 160 mgals., found on the Pacific coast of the northern part of the Ibaraki Prefecture, while the lowest of −30 mgals. is found about 25 km. to the southwest of the city of Tôkyo. Towards the northeast of Tôkyo, the BOUGUER anomaly increases very remarkably. In its steepest part, the increase reaches even 140 mgals. per 40 km., that is 35 Eötvös on average. The gravity gradient of this magnitude is not uncommon in those areas where the gravity fields are very much disturbed by the existence of ores

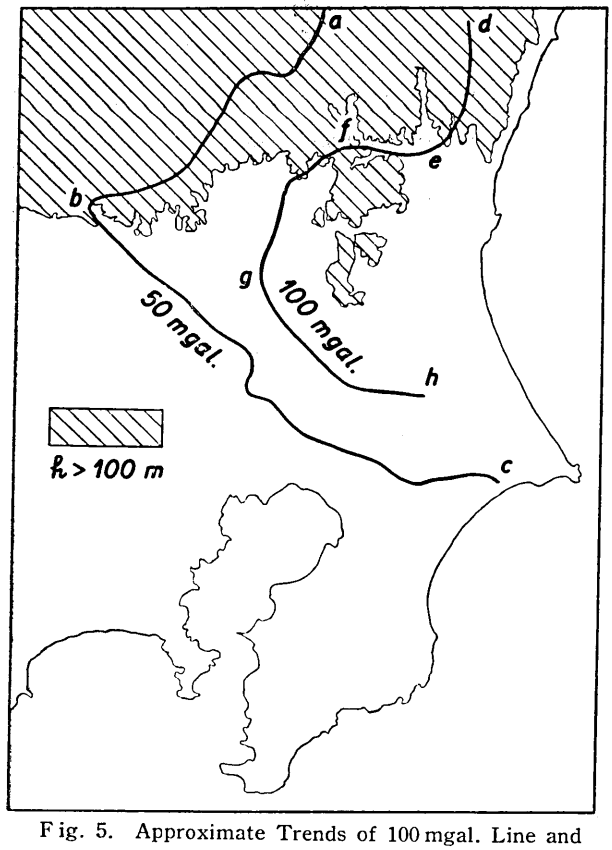

Fig. 5. Approximate Trends of 100 mgal. Line and 50 mgal. Line in the Kantô District.

of economic value, but these are usually localised within a narrow zone of 10 km. or so in width. The steep gradients of gravity anomaly that have been found here in this District are much more regional in character and need considerably anomalous underground structure for them to be explained.

2) In the north-eastern quarter of the Kantô District, the BOUGUER anomalies are decidedly high. Tracing the contour line of 50 mgals., for instance, its trend (abc) is seen to change sharply from NS to EW in the form of the letter L, as shown in Fig. 5. The part (ab) is the natural southward elongation of the Morioka-Shirakawa line which was proposed in the seventh of our serial reports. As was stated before, the Kantô plain is widely covered by Pleistocene and Recent geological formations and there is no direct geological evidence that can be taken as indicating the existence of a discontinuity in the underground structure beneath (abc). Embraced by the line (abc), there is hilly mountain range, shaded in Fig. 5, running NS and consisting of Palaeozoic formation intruded by granite. It seems likely that this heavy mass slopes down into all directions except into N. At a certain depth, the slope of the surface of this mass must be suddenly increasing as shown in Fig. 6. This part is overlaid by young sedimentary formations so that no geological manifestation of this abrupt change in the underground structure can be observed.

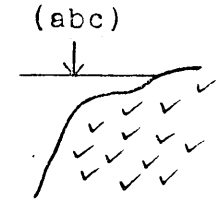

Fig. 6. Profile showing the Supposed Underground Structure beneath (abc).

3) The contour line of 100 magls. follows (defgh) in Fig. 5. The part of the line (ef) in Fig. 5 is characterised also by steep gradients of gravity anomaly across it and suggests another remarkable underground discontinuity. But, to the best of our knowledge, there is hardly any geological evidence for its existence.

4) A little to the south of the city of Tôkyo, there is an area of gravity low in the form of an ellipse elongated in the EW direction. This gravity low undoubtedly indicates a depression of the earth's crust. It is interesting to note that it is exactly here in the ellipse that moderate earthquakes having depths about 50 km. very frequently take place. For instance, T. KODAIRA (1933), T. NAGATA (1936), and N. NASU, T. HAGIWARA and S. OMOTE (1936) clearly stated that there are two distinct groups of epicentres in the Kantô District, one of which corresponds to the area of gravity low just mentioned. The other group is just along the line of the steep gravity gradient stated before.

5. Acknowledgements

We cannot close this report without expressing our sincere gratitudes to the many officials and individuals who have helped us in various ways in accomplishing this survey. It is almost impossible to mention the names of all these persons. Particularly, we wish to thank Mrs. S. INOUE and Mrs. K. SEKI who have helped us greatly in numerical computations and in preparing the present paper. The necessary expense for executing the present survey was partly defrayed from the Grant in Aid for Scientific Research from the Ministry of Educations.

ウォルドン重力計による日本全国の重力測定

第八報 (関東地方)

坪井忠二・実川 顕・田島広一

これは，関東地方 366 点における重力測定結果をまとめたものである．測定と計算との方法は，第 1 報に述べてあるのとほとんど同じであるから，ここにはくりかえさない．結果は第 III表～第 IX 表 (ルート別)，第 X 表～第 XVI 表 (県別) に示してある．ブーゲー異常の分布は，第 3 図にくわしく示してある．第 4 図はその略図である．

これらの図からわかる主なことがらは，次のとおりである．

1) 関東地方は，地形からみると，だいたい平地であるが，ブーゲー異常の分布は非常に複雑である．最高は茨城県北部の太平洋岸にみられる +160 mgals., 最低は東京の南西 25 km のところにみられる −30 magls. である．東京から北東にむいて，ブーゲー異常は急に増していて，その割合は 35 Eötvös にも及ぶ．これを説明するためには，著るしく異常な地下構造を考えなくてはならない．

2) 関東地方の北東部では，ブーゲー異常は決定的に高い．+50 mgals. の線は L 字型をして北南から西東に方向をかえている．(第 5 図)．ab は盛岡，白河線の続きである．この辺りは若い地層におおわれているから，地下の不連続構造 abc を示すような直接の地質学的証拠はないと思われる．筑波山地は，この abc 線に抱かれている形になつているが，この山地を作つている岩体の表面は，第 6 図のように，ある深さで，南，西にむかつて急に傾き落ちているにちがいない．この急傾斜のまうえが abc 線にあたるのだと思われる．

3) 第 5 図の ef 線 (100 mgals. の線の一部) のところでも，ブーゲー異常は急に変化していて，地下に何か異常な構造が存在することを示している．しかし，それに対する地質学的の証拠はないようである．

4) 東京の南西方に，ブーゲー異常がマイナスの地域があつて，東西にのびた楕円形をしている．これは明らかに地殻の陥没を示している．この場所が地震の頻発地域と一致していることは興味深い．
