Abstract

The three components and total intensity of the geomagnetic field were measured using STCM and a proton precession magnetometer during the DELP 1987 Ogasawara cruises. The total intensity anomalies are generally negative and small in amplitude in the trough, their lineation pattern can hardly be defined. However, the anomaly patterns of the three vector components of the geomagnetic field show widely distributed lineation features trending north-south over the trough. Two total intensity negative peaks in the northern and southern ends of the trough are located at around the same positions as the free air gravity negative anomaly peaks.

1. Introduction

In the Ogasawara (Bonin) Trough, geological and geophysical surveys have been carried out by many institutions. Among them the Geological Survey of Japan has made intensive surveys since 1979 (eg. MIYAZAKI *et al.*, 1981) and the Hydrographic Department of Japan Maritime Safety Agency also conducted intensive surveys along a series of track lines running north-south separated by 5 nautical miles from each other between 24 and 27 degrees north latitude including a sea-beam mapping survey (KASUGA

et al., 1988).

The trough carries a thick sedimentary sequence with unconformities, evidence of complicated tectonic development. HONZA and TAMAKI (1985) proposed that although the Ogasawara Trough is presently inactive in the fore-arc area, the trough had opened during the early to middle or late Oligocene. They proposed also that this sequence could be associated with the collision of the Ogasawara Plateau against the Ogasawara Island Arc; the opening was explained by tectonic erosion of the subducting Pacific lithosphere.

The objectives of the magnetic survey in DELP cruises were to aim at studying following problems.

1. Identification of magnetic anomaly lineations,
2. Determination of magnetization of the Kaikata Seamount.

Objective 1 is particularly designed for finding evidence of opening processes in the trough, and objective 2 is for obtaining some information about tectonic movement (migration and rotation) of the crustal material (Kaikata seamount) which is located on the eastern flank of the Shichito Iwo-Jima Ridge.

2. Method of Measurement

Three components and total intensity of the geomagnetic field were measured by STCM (Shipboard Three Component Magnetometer; ISEZAKI, 1985) and a proton precession magnetometer. The positioning of the survey ship were obtained by LORAN-C and occasionally by NNSS, and/or GPS (of sattelite system) and, at the same time, the bathymetric water depths were measured by a Precision Depth Recorder (PDR). All these data were provided in a form of digital data which were transferred and saved on a floppy disk controlled by a portable desk top micro-computer.

The STCM was set up on the deck during the entire cruise period and the field around the magnetic sensor may have been affected by the additional magnetic fields produced by the metallic body of the research vessel. The true geomagnetic field was calculated by subtracting this field from the original field value. We measured this bias magnetic field induced by the ship by spinning the heading of the vessel by 360 degrees when we moved a certain distance in the north-south direction several times during the cruise (ISEZAKI, 1985).

Magnetic field values, i. e., total force, and three vector components were compared to those of IGRF-85 (International Geomagnetic Refernce Field determined in 1985; IAGA DIVISION I, WG 1, 1985) and the local

geomagnetic anomalies were derived by subtracting both the general regional field and artificial biasing field.

3. Results

3-1. Magnetic anomaly lineations

The magnetic survey was conducted on three zigzag courses across the basin (Fig. 1) for finding the magnetic lineations. These tracks are limited to the southern half of the trough between $25^{\circ}30'N$ and $26^{\circ}30'N$; there is only one track traversing the trough in the northern part along about $28^{\circ}45'N$ latitude. It was found along these zigzag tracks that there exist

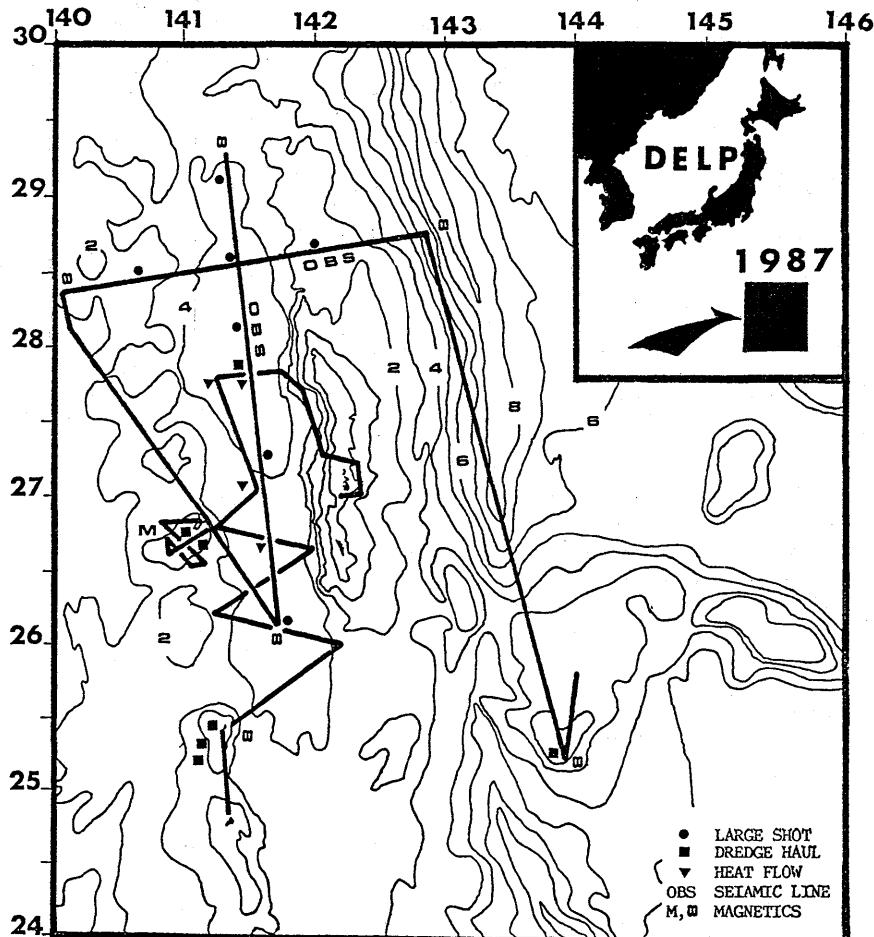

Fig. 1. Tracks of DELP cruises in the Ogasawara Trough. The bathymetric contours are at 1000 m intervals.

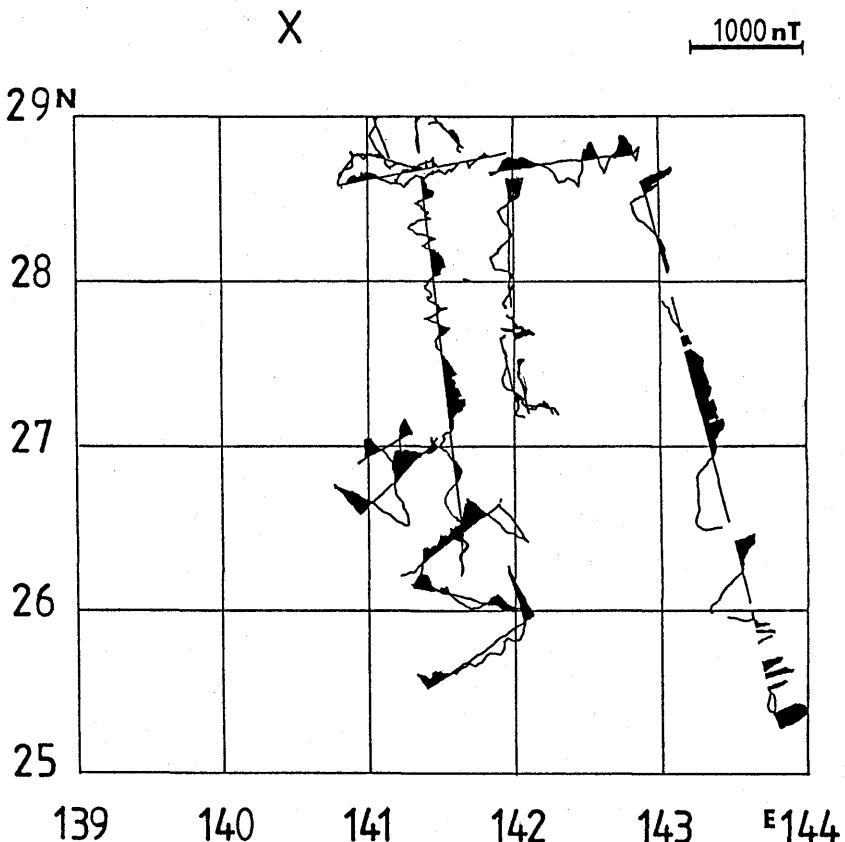

Fig. 2(a)

Fig. 2. Magnetic anomaly profiles along tracks for measuring the three component and total intensity anomalies.

a: Northward component (X); b: Eastward component (Y); c: Downward component (Z) and d: Total intensity P obtained by Proton magnetometer. Relative scale of amplitude of the field intensity is given by a horizontal bar of 1000 nT, on the top right side of each figure. Coordinates are given in degrees latitude and longitude. Track lines are referred to in Fig. 1.

clear lineations in the magnetic anomaly in Y and Z components in the southern part of the trough (Figs. 2b and 2c). The strike of lineation is nearly north-south; therefore, the X (geographical north) component anomaly of the geomagnetic field contributes little to the anomaly value (Fig. 2a).

We have one track line traversing the trough from east to west at about $28^{\circ}45'N$ (Fig. 1). To see the correlation of magnetic anomaly pattern between the northern and southern parts, anomaly profiles along this track ($28^{\circ}45'N$) together with the southern zigzag tracks are presented in

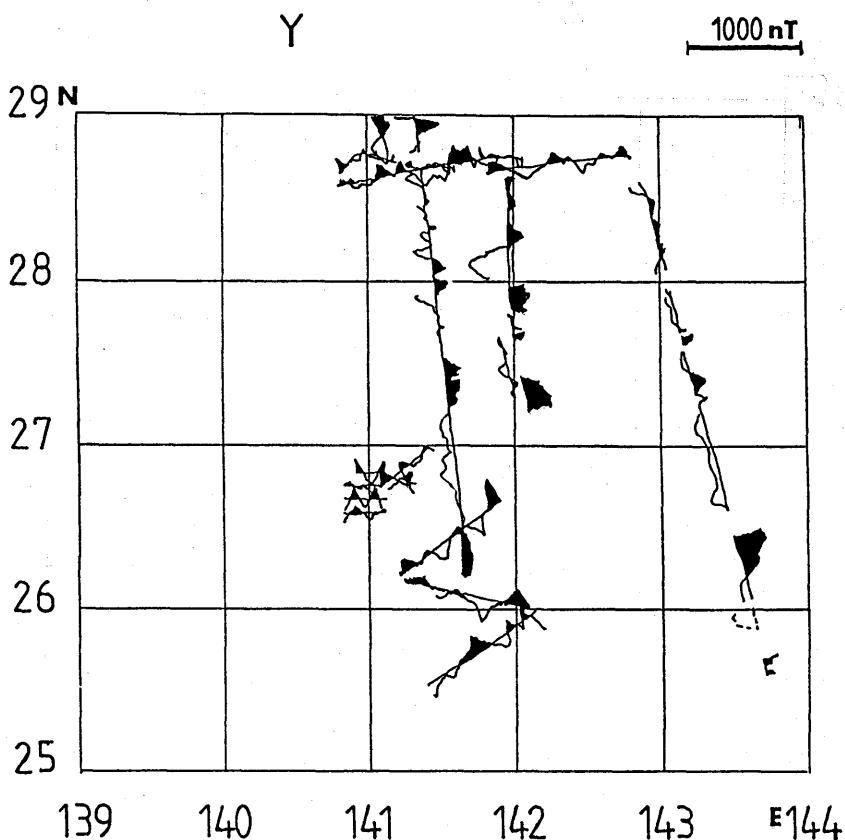

Fig. 2(b)

Fig. 3.

We conclude from these patterns that there are magnetic anomaly lineations which are continuous from the northern part to southern part of the trough area. This pattern is incorporated into the other geomagnetic measurements obtained by the Geological Survey of Japan (HONZA and TAMAKI, 1985) in which we can see a continuous trend of vague negative anomaly in geomagnetic total force running all through the trough area from north to south. We, therefore, consider that the magnetic anomaly patterns of three components of the geomagnetic field obtained by the present survey are also ubiquitous in the entire trough area.

We could not recover some part of the total intensity anomalies measured solely by a proton magnetometer on board of R/V Tokaidaiigakumaru Nisei due to its occasional hardware malfunctioning on these zigzag tracks. There is, however, a large number of data of total intensity of

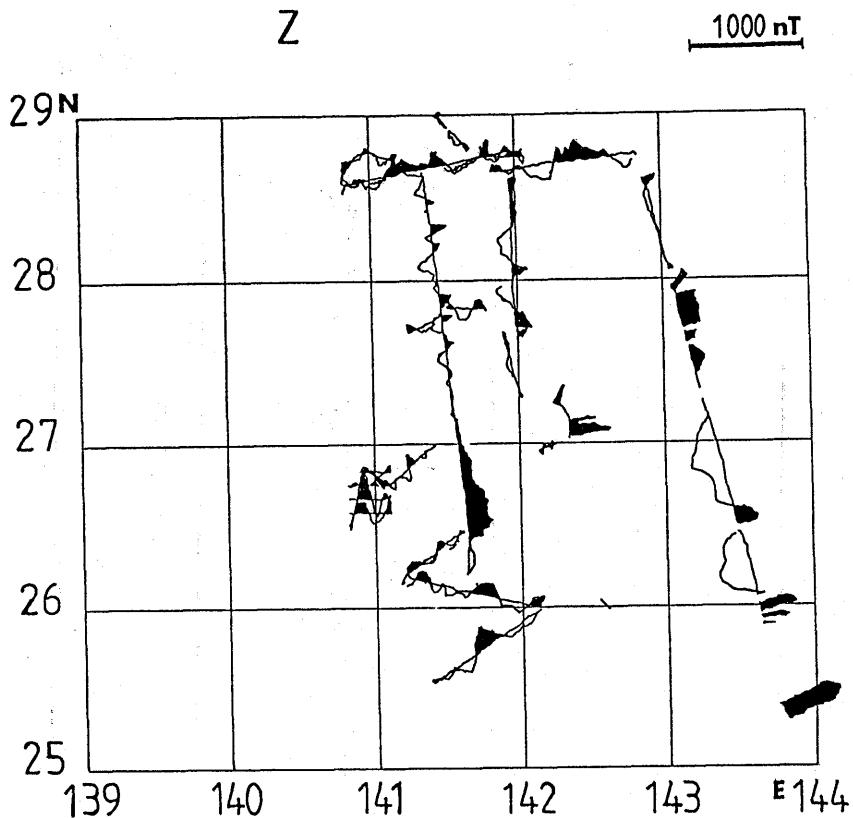

Fig. 2(c)

the geomagnetic field in the Ogasawara Trough to correct the defect in the present survey.

There is no good report on the systematic lineament of the geomagnetic field anomaly in the whole area of the trough to date. It is easy to show the difficulty of extracting any magnetic anomaly value of the geomagnetic total field intensity based upon a fact that the low angle of inclination of the geomagnetic field induces only a small component deflecting the ambient field. Because the strike of lineation is in general along the north-south direction, we could detect clearly only Y and Z component anomalies. Supposing that the magnetic body under observation extends to infinity in horizontal spread, the Y (E-W) component anomaly does not contribute to the total intensity anomaly. However, the Z component anomaly contribute to the total intensity anomaly, even if it is small. Even in case the inclination of the local geomagnetic field small as in the present case (dip angle: 37°), the deviation in the vector component Z is

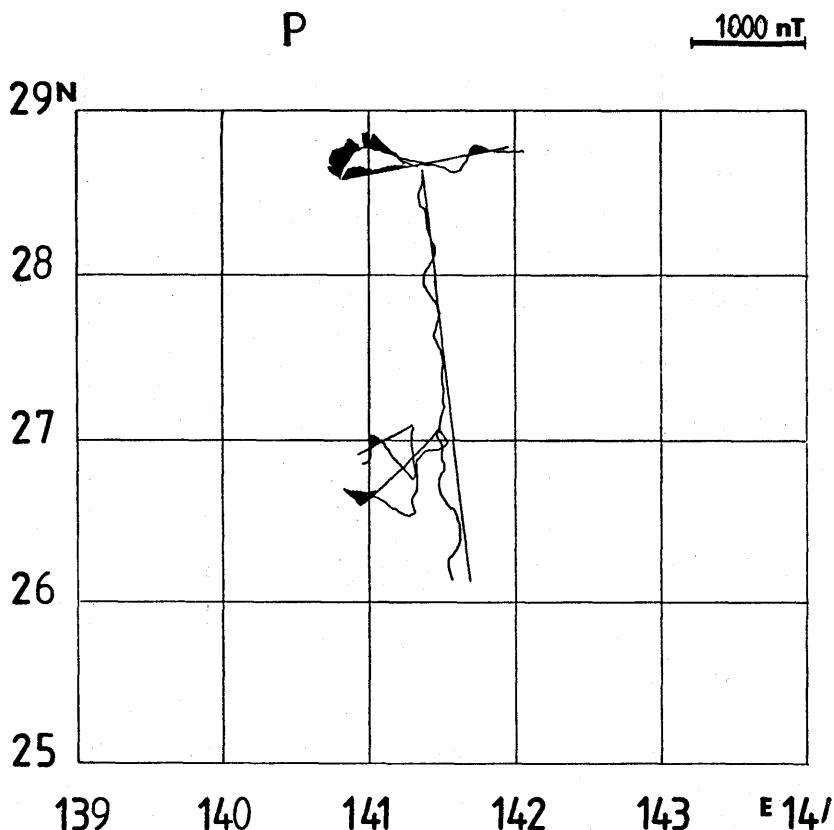

Fig. 2(d)

clearly definable. However, if we try to deduce the anomaly amplitude in the total geomagnetic intensity, it becomes less pronounced and gives rise to 0.6 times the amplitude of the vector component anomaly intensity.

3-2. Kaikata Seamount

This seamount is located on the volcanic front, the Shichito-Iwojima Ridge, about 65 km south of Nishinoshima Island which is presently active. The Shichito-Iwojima Ridge is characterized by many en echelon segments aligned northeast to southwest. These faults are believed to be remnants of old shear zones of Tertiary period (YUASA, 1983). It can be shown that this seamount had undergone some tectonic rotation based on the declination of magnetization. We can also find the latitudinal migration of the seamount from the inclination of magnetization, important information on the tectonics of the Philippine Sea Plate.

Although not all magnetic data on Kaikata Seamount have been ana-

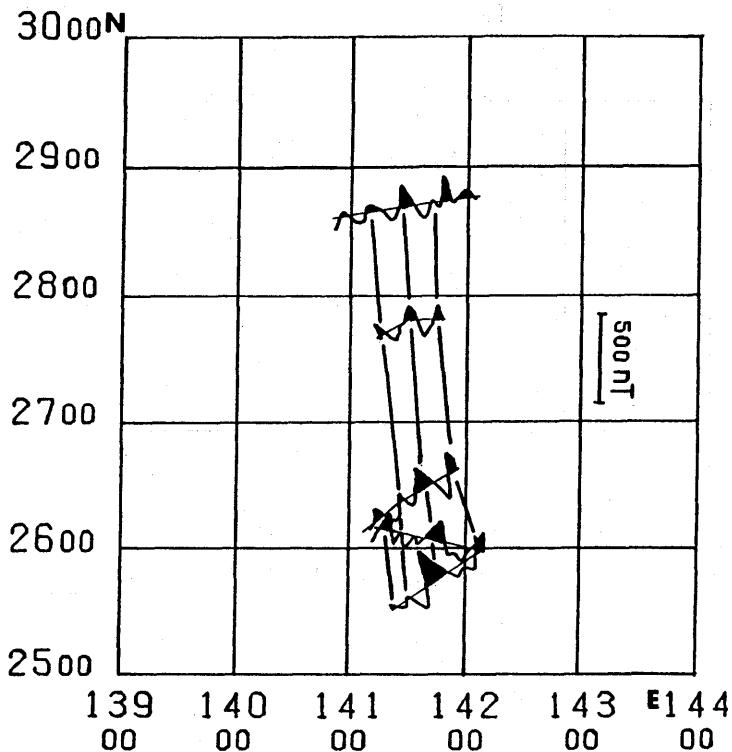

Fig. 3. Identification chart of the magnetic anomaly lineation patterns based on Z-component anomalies in the Ogasawara Trough area.

lyzed yet, two of the authors reported the tentative result of magnetization of this seamount using only total intensity anomalies, that is, -43° in declination and 50° in inclination (Fig. 4a and 4b) (ISHIKAWA and DEN, 1988). There values do not agree with those suggested by the tectonics of the Shichito-Iwojima Ridge and the Philippine Sea Plate: clockwise rotation and northward drift in general. This discrepancy may be due to three cases: poor quality of magnetic total intensity data, insensitivity of total magnetic field to anomaly configuration, or this seamount tilted in an isolated way from surrounding structures. We plan to analyze three component and total intensity data measured by this cruise (R/V Wakashio-maru).

3-3. Relation to gravity anomalies

There is a positive free air gravity anomaly amounting to 380 mgal over the northern part (ca 28°N) of the Ogasawara Ridge. To the southwest in the Ogasawara Trough (23.3°N), there is also a large negative

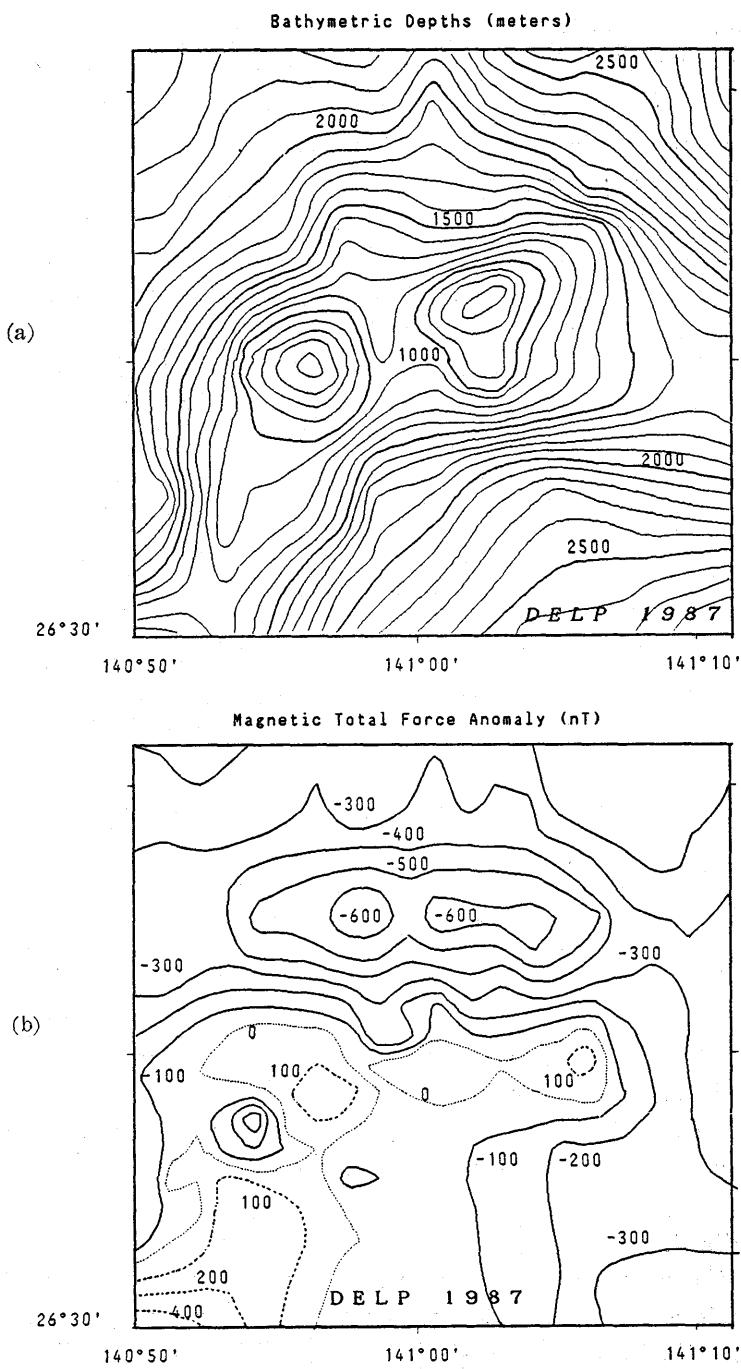

Fig. 4. Bathymetry and distribution of total force magnetic anomaly around the Kaikata Seamount. The location of these figures can also be referred to in Fig. 1. a: Bathymetry with contour lines every 100 meters. b: Magnetic total force anomaly every 100 nT reduced to IGRF85 (IAGA Division I, WG 1, 1986).

free air gravity anomaly of -120 mgal. (ISHIHARA *et al.*, 1983; GEOLOGICAL SURVEY OF JAPAN, 1982). The minimum anomaly of -120 mgal is located at about $26^{\circ}10'N$ in the trough, ca. 220 km to the west of the western edge of the Ogasawara Plateau which is presently colliding against the Ogasawara arc.

As for the total geomagnetic intensity anomalies, there are generally negative anomalies with low amplitude in the entire trough area. The minimum anomaly of about -200 nT is located at almost the same position ($26^{\circ}10'N$) as that of the minimum (negative) free air gravity anomaly. There is another weakly negative free air gravity anomaly peak of -60 mgal at about $29^{\circ}40'N$ in the northern part of the trough and also a negative peak of geomagnetic total intensity anomaly of about -200 – 500 nT at the same position (GEOLOGICAL SURVEY OF JAPAN, 1982). The bathymetric depth of the trough at around $26^{\circ}10'N$ and $29^{\circ}40'N$ are about 3500 m, while the deepest part of the trough is between these two points, around $28^{\circ}00'N$ where the sea depth is about 4150 m. These facts play an important role for discussing the crustal structure beneath the trough. The depression of the basement will usually decrease the intensity of magnetic total force anomaly if magnetization of the magnetic basement is induced by the geomagnetic field. However, the relation among magnetic anomaly, free air gravity and bathymetric depths in this trough does not seem to follow this general tendency and leaves us to do an interpretative simulation experiment in our further study.

Acknowledgment

Authors are obliged to crew members of the R/V Tokaidagakumaru Nisei, Tokai University as well as R/V Wakashiomaru, Nippon Salvage company for their help and suggestions on data acquisition and ships operation during the present surveys. Thanks are also due to many students of Tokai, Kobe and Chiba universities for their help in data acquisition, data processing and collection of necessary materials.

Appendix 1.

During the magnetic measurements, the research vessel was turned around occasionally to check the varying intensity of the permanent and induced magnetizations of the steel vessel. This measure allow us to remove the spurious field of the ship's body afterward by software in addition to actual geomagnetic field components. The positions and times of this routine operation are listed below.

Date and Time month-day-hour/min.	Latitude (deg-min. N)	Longitude (deg-min. E)
11-04-14/11	34-21.10	138-39.92
11-06-05/42	29-20.11	141-13.94
11-07-09/13	26-09.55	141-40.64
11-08-04/53	28-26.41	139-59.21
11-08-15/22	28-35.89	141-22.92
11-09-08/38	28-43.78	142-50.90
11-10-07/43	25-14.59	143-48.80
11-12-14/43	25-30.07	141-20.63

Appendix 2.

A list of field data of the three components of the geomagnetic field, total geomagnetic intensities and bathymetric depths are presented. We have to notice that the total intensities obtained by R/V Tokaidaigakumaru Nisei are less reliable due to occasional malfunctioning of the data acquisition system during the whole cruise.

The list includes (from left to right blocks) ;

- 1: Sample time (year/month/day/hour/minute : i. g. 87 11 8 9 2)
- 2: IGRF-85 based deviation values of three comonents of the geo-magnetic field (North/East/Down in nano Tesla, e. g. 35 -68 -17)
- 3: Total intensity (nT, e. g. 45536.0 ; six 9 figures indicate no-data)
- 4: Ship's position in latitude (degree/minute) and longitude (degree/minute, e. g. 35 12.36 139 46.24)
- 5: Water depth (meters, e. g. 2135 ; five 9s indicate no-data)

Data are presented every 10 minutes for the entire period of the present cruise. The first half of the record (Part I: from Nov. 8 through Nov. 20) was obtained by R/V Wakashio-maru and the other half (Part II: from Nov. 11 through Nov. 20) by R/V Tokaidaigakumaru Nisei.

DELP 1987年度 小笠原海域航海報告

V: 地磁気三成分及び全磁力異常分布探査

神戸大学理学部地学科	東海大学海洋資源学部	伊勢崎修弘

		市川浩也
		高橋克也
		高井上康子
		杉本恭子
		石川秀浩

1987年秋の DELP 航海により小笠原トラフ周辺海域において地磁気連続測定を行った。測定に於いては船舶用フックスゲート地磁気三成分測定系ならびに曳航型プロトン磁力計により観測を行ったが、後者については航海中船上測定系に異常が出たことなどもあって完全な三成分対全磁力比較検討の材料とは成らなかったものの、全磁力についてはこの海域に於て地質調査所などから多くのデータが提供されているので、解析に支障は無いと思われる。

船舶上での三成分磁力測定はかねてから神戸大学理学部により信頼度の高いデータが得られる様に成ってきたが、本観測地域の例にもみられるように低緯度でかつ海底の基盤もまた低緯度で発生したと予測される地域の地磁気観測には三成分磁力計は必要不可欠なものである。この報告にも、従来より明瞭な地磁気縞模様の認められていなかったトラフ内にもその存在が確認されたことは、トラフがリフティングとオープニングによって形成されたことを示唆している。今後この縞模様が何時のものであるかを同定せねばならないが、そのためにはこの海域の基盤岩の年代などに関する資料を入手したいと考える。
