ABSTRACT

Archosauria is the least inclusive clade containing living crocodiles and birds and radiated extraordinarily during the Mesozoic. This clade consists of highly diverse extinct species, many of which differed substantially from their extant relatives in morphology. In their evolutionary history, archosaurs display a trend toward increasing bipedalism, that is, the forelimbs tend to be reduced in contrast to the development of the hindlimbs becoming major weight-bearing and locomotor appendages. The limb morphology is the most informative in understanding the locomotor modes. Since Romer's pioneering work on the limb anatomy and myology, archosaur locomotion has been extensively discussed in paleontology and comparative biomechanics. In addition, the recognition of extant birds as the direct descendants of Mesozoic theropod dinosaurs has led to further understanding of major evolutionary changes in the limb morphology and function in the entire evolutionary history of Archosauria. Despite numerous attempts of reconstructing the hindlimb musculature in archosaurs, the most distal portion, the pes, has often been neglected.

In order to infer evolutionary changes in the pedal muscles, their detailed homologies among reptilian taxa, as well as osteological correlates of their attachments on the skeleton, were established based on dissections and literature reviews. As a result, the homologies of *m. tibialis cranialis* and *m. extensor digitorum longus* between non-avian and avian reptiles were revised, challenging the classical interpretations. The new hypothesis in which the avian *m. tibialis cranialis* and non-avian *m. extensor digitorum longus*, as well as the avian *M. extensor digitorum longus* and non-avian *M. tibialis anterior*, are homologized is more plausible because it requires no difference in the attachment sites between the avian and non-avian homologues unlike the classical hypothesis. In addition, many dorsal and plantar interosseous muscles that have previously been regarded as a part of the short digital extensors or flexors were divided into multiple distinct muscles in non-avian reptiles as a result of the present study. These subdivisions previously unknown for non-archosaurian reptiles have enabled the comparison of short pedal muscles between non-avian reptiles and avians.

To reveal the evolutionary history of the musculoskeletal complex of the pes, the morphology of the hindlimb skeleton was examined in a broad range of fossil archosaurs with a particular emphasis on the osteological correlates of the musculature.

As a result, many osteological correlates were recognized, and most of them present in basal archosaurs appeared to have been displaced or disappeared in their evolutionary history toward extant birds over the past 250 million years.

Based on osteological correlates, the evolutionary sequences of the pedal musculature among archosaur lineage were inferred with a focus on theropod dinosaurs, with the ancestral state successfully reconstructed on each node on the line to birds. The transition of the pedal muscle morphology from the ancestral to derived conditions was revealed to have occurred sequentially along the lineage of bird-line archosaurs. However, the acquisition of erect, digitigrade and bipedal posture in basal ornithodirans was inferred to have been associated with the reduction of the plesiomorphic device for reducing the bending moment of the pes. In contrast, although the ‘knee-driven’ locomotion would have been aided by the lightened distal limb, the reduction of the muscle mass in the pedal region appears to have occurred as a further optimization of the plesiomorphic, hip-driven locomotion through reduction of the energy required for the stride cycle. Although the present study was focused on the anatomy of the pes as a clue for tracing the evolution of the pedal locomotor function in Archosauria, the pedal muscle reconstructed here will also contribute to refining the kinematic analyses. Moreover, further study on the reconstruction of other soft tissues of the pes will contribute to connecting skeletal and ichnological data and revealing the evolution of locomotor traits in Archosauria.

ACKNOWLEDGEMENTS

Because many people contributed to the present study and my discipline and motivation to work on this field of research, I am sure to forget a few of them or to make some errors within this section. I apologize them in advance, and am assured that if anyone is omitted from mention or incorrectly described here it is a result of the failings of my memory and does not mean their negligibility.

Foremost, I wish to thank my supervisor Takanobu Tsuihij, whose support in all aspects and outstanding opportunities provided to me over the years has been fundamental to my learning the science. He has had a part in all aspects of this work and his influence extends distantly beyond having read every part of this dissertation. I especially thank him for providing opportunities to dissect many kind of reptilian specimens in his care, from which I obtained the most important information to form the foundation of the present study. I would feel myself a success if I could be only half the advisors to others that he has been to me.

Thanks also to following committee members for patiently awaiting this work. I am grateful to my advisors, Kazuyoshi Endo and Takenori Sasaki, for encouragement and many useful comments throughout this project at the University of Tokyo. I am particularly indebted to Makoto Manabe for permission to use CT facilities at National Museum of Nature and Science, Tokyo. I also thank to Hideki Endo for permission to dissect a crocodylian specimen housed in the Research Museum, the University of Tokyo. Thanks go to Daisuke Suzuki for sharing unpublished data on crocodylian myology.

For access to fossil specimens in their care, I wish to thank individuals at a number of institutions: Mark Norell and Carl Mehling (AMNH); Shinobu Ishigaki and Shigeru Suzuki (HMNS); Stella Alvarez, Alejandro Kramarz and Julia Desojo (MACN); Sandra Chapman and Lorna Steel (NHMUK); Jaime Powell (PVL); Rainer Schoch (SMNS); Patricia Holroyd (UCMP); Randall Irmis and Carolyn Levitt (UMNH); Daniel Brinkman (YPM). Additional thanks are due to the Japanese (HMNS) and Mongolian (MPC) researchers for allowing access to fossil specimens found through their joint expeditions. I extend many thanks to Junko Takayama (Chiba Biodiversity Center, Nature Conservation Division, Environmental and Community Affairs Department, Chiba Prefecture) for providing specimens of *Chelydra serpentina*,

Hidetoshi Ohta (Museum of Nature and Human Activities, Hyogo, and University of Hyogo) for providing specimen of *Iguana iguana*, and Yuko Iima (Kushiro City Zoo) for providing specimens of *Grus japonensis*.

Funding was provided for parts of this work by the Japan Science Society, the Jurassic Foundation, and the Japan Society for the Promotion of Science. I acknowledge their significant contributions.

Finally, I acknowledge my family and friends for their continued support. My parents, Shinji and Etsuko, and my sister, Kei Hattori helped me in innumerable ways throughout my life and waited a long time to see this work completed. Thanks go to colleagues and friends at the University of Tokyo or other institutions, for providing great encouragements, various critical comments and technical assistances for this work.
